A trade EMS for on-chain capital, where the agent's reasoning is a database query away.

Constraint-bounded agents reallocate capital against quantile forecasts, and every decision traces to the projection that justified it. The execution is real today; the audit trail is the part nobody else builds.

$304M / yr TAM at 25 bps on managed on-chain capital	**$11.9M / yr** SOM at 5% of the crypto fund segment, 3–5 years	**29** contract tests, and 21/21 registry addresses verified on two chains	**$300K** twelve weeks, to v1 and the first desks

Product

Three layers, and they are at three different stages of being built. Naming that is the first honest thing this memo can do.

- **The terminal** — a desk and a console for an operator holding capital on-chain. Live. An operator asks a question; an agent runs a five-node cycle; the answer, the forecast behind it and the guardrails that gated it all land in one surface.
- **The infrastructure beneath it** — forecast (TimesFM-3 quantile projections in a ledger), decision (the agent cycle), risk (typed constraints that can force a re-plan), custody (a Safe owned by an embedded signer), settlement (Aqua/SwapVM, Uniswap v4, 1inch, Morpho). Built and running, with the gaps listed on page 3.
- **The instrument** — the web3-aligned ETF wrapper. This is the market this is infrastructure *for*, and it is not built. It is named here so that no reader discovers the omission later.

What the product actually does, worked once

A strategy's yield falls under its floor, or its volatility breaches its cap, and the position flees. The volatile leg swaps to a stablecoin through a `SwapVM` program containing **an instruction we wrote** — `YieldBandFlight` at opcode `0xb3` — and the proceeds are deposited into a Morpho vault. The whole thing is two Aqua apps, deliberately separate: a router that is a canonical `SwapVM` plus our instruction, and a refuge app that "holds no pricing logic at all; its whole job is that one call moves both legs back to the maker, which removes the window of half-executed risk between the swap and the deposit."

That is the product's unit of work: an intervention calibrated to one moment, executed atomically, dissolved. The deck calls this product:moment fit, because that is the term the Machine Economy thesis uses for it and it is exactly what this is.

Why now

> Any two of these inventions without the third, and you hit a ceiling.
>
> FABRIC VENTURES — THE THREE CONVERGING INVENTIONS

Specialised accelerated compute means a quantile band per pool, per request, in under a second. Large language models mean an agent that can read a constraint set and propose a reallocation inside it. Programmable blockchains mean settlement with no intermediary and a receipt for every action — **the audit trail is native to the substrate rather than bolted onto it.**

The standards that close the loop have landed recently:

- **ERC-8004** — agent reputation portable across counterparties (mainnet, January 2026).
- **EIP-4337** — account abstraction; 26M smart wallets and counting.
- **Scale** — $27.6T settled on-chain in 2024, rivalling Visa and Mastercard combined; and by May 2026 a Chainlink × Ark Invest report put autonomous agents at roughly **30% of TVL in top-tier DeFi pools**.

That last figure is the reason this company should exist now rather than in 2022. The capital is already a third machine-managed. The tooling around it is not.

Market

Sized three ways, all three reported, because a single method is a guess with a number attached.

METHOD	WORKING	RESULT
Top-down — fee pool on professionally managed on-chain capital	$95.0B crypto hedge fund AUM + $26.7B managed tokenized/RWA, at 25 bps	**$304M / yr**
Bottom-up — the segment that rebalances	400+ crypto hedge funds at a mean $237M, at 25 bps. The split between funds that trade on-chain and those that hold is `[share of funds that trade on-chain]` — unsourced, so not guessed	**$237M / yr**
Value theory — what a desk pays to not lose a position to a missed band	At 100 bps — what an actual manager charges — the same capital is $1.2B/yr, and the question becomes what share of the management fee an execution-and-risk layer defends	**$1.2B / yr**

The near-term business is a $5–12M ARR opportunity at 2–5% penetration of the fund segment. That is real and it is not a decacorn, and this memo will not pretend otherwise. What makes it large is the ETF layer, where the capital base is orders of magnitude bigger — `[tokenized fund market, sourced]`, a figure we could not source and therefore will not quote. The ceiling of $21.5T a year in stablecoin volume is not quoted either: 88% of it is exchange trading, bots and arbitrage, which is flow we do not serve.

Competition

Brava Finance is the closest competitor and the deck names it. An institutional platform for allocating stablecoin and tokenized credit: real-time risk scoring, mandate automation to codify allocation policies, cross-chain execution across DeFi and RWA, audit-ready reporting, non-custodial execution from the allocator's wallet via Safe. That is our custody model and our pitch, largely.

The difference is two words, and both are checkable in the code:

- **Policy versus forecast.** A mandate is a static rule. Ours is a quantile forecast with a confidence band that decides when the band is breached — q10/q50/q90 in a forecast ledger, with calibration measured against realised yield.
- **Reported versus required.** Their audit is a report *about* decisions. Ours is a schema a decision cannot be written without: `citations: z.array(...).min(1)`. An ungrounded answer degrades to an explicit `HOLD` marked `ungrounded` rather than passing quietly.

The honest positioning is therefore **forecast-driven × structurally required**, not "automated and accountable" — because that quadrant is not empty, and claiming it would be the first thing a careful reader checks and disproves. The third category of alternative, which pitches usually omit because it is unglamorous and correct, is **non-consumption: a human with a multisig, a spreadsheet and a Telegram thread.** That is the incumbent, it is free, and it is what this has to displace.

Traction, in the only currency we have

No users, no revenue, no LOIs. What exists is a working system and evidence that can be re-derived by a stranger.

CLAIM	METHOD
21/21 registry addresses verified against live chain state, on Optimism *and* Polygon	`pnpm run smoke`
`quote(amountOut)` ≡ `swap(amountOut)`, and the fill landing exactly on the band — 3,400 USDC for 1 WETH	`fork test`
29 contract tests with no network	`forge test`
`0xb3` provably ours — the same program runs on our router and reverts `UnknownOpcode(0xb3)` on the canonical one	`OpcodeOwnershipTest`
The guard is inert when unarmed	`paired negative test`

Reproducible at a pinned fork block, with the evidence committed to the repository. `[traction]` — add anything not already in the repo.

The team

Dhruv Malik — founder. Six years as a Web3 protocol engineer and smart-contracts auditor, and co-founder of Extra Labs, a geospatial 3D reconstruction platform. He has shipped and audited the execution half of this product before: protocol code, custody paths, and a record that has to be right the first time.

Specialists, in discussion. `[specialist name]`, a former fixed-income trader who went on to run DeFi at a major L2 chain, owns the half a protocol engineer cannot claim alone — how a desk sizes, hedges and defends a position when the band breaks. `[mentor name]` spent five to six years as a fixed-income trader at Bloomberg, building some of the terminal's most complex components, multi-asset risk synthesis among them, and advises on the risk layer the guardrails are built from.

What we know is missing

Taken from the repository's own documentation, where it is already written this way. An investor who finds these unaided will trust everything above less.

1. **Nothing is fully committed yet.** The work exists as reviewed changes rather than a clean history; 22 atomic commits are planned. Process, not engineering.
2. **Intent persistence is missing.** The intent table carries the typed-data hash that binds a signature to the payload an operator actually reviewed, and nothing writes or reads it — so an intent's identifier is currently a caller-supplied handle rather than a reference to something that was reviewed.

3. **Custody caps are not enforced.** Per-transaction and daily caps and the allowlist exist as schema, and nothing consults them. Enforcing them needs the store above.
4. **Position creation is unencoded, deliberately.** The entry point is an actions batch whose command bytes could not be retrieved, so it was left rather than guessed — a wrong byte executes the neighbouring action.
5. **The ETF wrapper does not exist.** It is the market, not the product.
6. **Two components render nowhere** and the risk snapshot store is unconfigured on the deployed surface, which the product says out loud rather than hiding.

The ask

$300K for twelve weeks, ordered so that each tranche funds the next and nothing is spent on presence before there is a version to show.

- **Build v1.** Inference and cloud for the platform's own research — research about the product, not our own AI workflows — and a minimal salary for a twelve-week base in SF or London.
- **Buy the room.** The Web3 events worth attending, promoted through Aladdin DAO, and a tutorial series that shows the system working rather than describing it.
- **Open the market.** From what remains: governance proposals to prominent lending protocols and a prediction market. Once v1 is live, sales engineering with the trading firms that already run Web3 desks.
